SHARP ESTIMATE OF THE REMAINDER
OF SOME ALTERNATING SERIES

Othman Echi, Adel Khalfallah* and Dhaker Kroumi

Abstract. For any two real numbers $\alpha > 0$ and $\beta > -\alpha$, we show that the best constants $a$ and $b$ (the smallest $a$ and the largest $b$) such that the inequalities

$$\frac{1}{2\alpha n + a} < \left| \sum_{k=n+1}^{\infty} \frac{(-1)^{k-1}}{\alpha k + \beta} \right| < \frac{1}{2\alpha n + b}$$

hold for every $n \geq 1$ are $a = \left( \frac{1}{\alpha + \beta} - S(\alpha, \beta) \right)^{-1} - 2\alpha$ and $b = \alpha + 2\beta$, where $S(\alpha, \beta) = \sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{\alpha n + \beta}$. In particular, we recover the main result of [6] and answer a question, stated in [6], about the Gregory-Leibniz series $\sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{2n-1}$. More precisely, we show that the best constants $c$ and $d$ such that the inequalities

$$\frac{1}{4n + c} < \left| \sum_{k=n+1}^{\infty} \frac{(-1)^{k-1}}{2k - 1} \right| < \frac{1}{4n + d}$$

hold for every $n \geq 1$ are $c = \frac{4}{4 - \pi} - 4$ and $d = 0$.

Keywords and phrases: Alternating series, estimate of the remainder of a series, hypergeometric series.
