

ON A CONJECTURE FOR THREE-DIMENSIONAL COMPETITIVE LOTKA-VOLTERRA SYSTEMS WITH A HETEROCLINIC CYCLE

MATS GYLLENBERG AND PING YAN

(Communicated by K. Ryu)

Abstract. For three-dimensional competitive Lotka-Volterra systems, Zeeman (1993) identified 33 stable equivalence classes. In this paper we show that: in the case of a heteroclinic cycle on the boundary of the carrying simplex of three-dimensional competitive Lotka-Volterra systems (class 27 in Zeeman's classification), the conditions (a) there is a pair of purely imaginary eigenvalues at an interior equilibrium, (b) the first focal value vanishes, (c') the second focal value vanishes, and (c) the heteroclinic cycle is neutrally stable do *not* imply (d) the third focal value vanishes. In particular, the conditions (a), (b), (c'), and (c) do not imply that the interior equilibrium is a center. This proves a conjecture by Gyllenberg and Yan (2009).

1. Introduction

In this paper we consider the three-dimensional competitive Lotka-Volterra (LV) system

$$\frac{dx_i}{dt} = x_i \left(r_i - \sum_{j=1}^3 a_{ij} x_j \right), \quad i = 1, 2, 3. \quad (1)$$

Recall that the assumption of competitiveness means that $r_i > 0$, $a_{ij} > 0$, $i, j = 1, 2, 3$. For such systems quite a lot is known. M.W. Hirsch [6] has shown that all nontrivial orbits approach a “carrying simplex” Σ , a Lipschitz two-dimensional manifold-with-corner homeomorphic to the standard simplex in \mathbb{R}_+^3 . This then leads to a Poincaré-Bendixson theorem for three-dimensional systems (see H.L. Smith [13]). Thus, the long-term behavior of system (1) is determined by the dynamics on Σ , and the nonzero forward limit sets in \mathbb{R}_+^3 all lie on Σ . Based on this result of Hirsch, M.L. Zeeman [16] defined a combinatorial equivalence relation on the set of all three-dimensional competitive LV systems and identified 33 stable equivalence classes. Of these, classes 1-25 and classes 32-33 exhibit convergence to an equilibrium for all orbits while limit cycles are possible for the remaining six classes, i.e., in classes 26 to 31 (see [14, 16]).

In the case of a heteroclinic cycle on the boundary of the carrying simplex Σ of a three-dimensional competitive LV system, we have (see Hofbauer and Sigmund [8]):

Mathematics subject classification (2000): 34C12, 34C23, 92D25.

Keywords and phrases: competitive Lotka-Volterra system, limit cycles, carrying simplex, heteroclinic cycle.

This project was supported by the Academy of Finland.

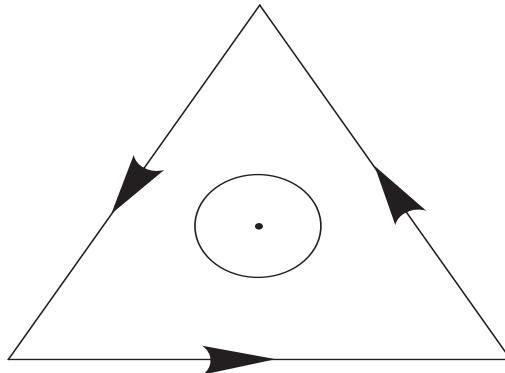

Figure 1: The phase portrait on Σ of class 27 with interior fixed point [16].

(i) the heteroclinic cycle is repelling if the characteristic number of the heteroclinic cycle is positive, i.e.,

$$P := \lambda_{12}\lambda_{23}\lambda_{31} + \lambda_{21}\lambda_{13}\lambda_{32} > 0, \text{ where } \lambda_{ij} = r_j - \frac{a_{ji}r_i}{a_{ii}};$$

(ii) the heteroclinic cycle is attracting if $P < 0$;

(iii) the stability of the heteroclinic cycle is undecided if $P = 0$.

Hofbauer and So [10] conjectured that, in the case of a heteroclinic cycle on the boundary of the carrying simplex, the following three conditions are equivalent to having a center:

- (a) there is a pair of purely imaginary eigenvalues at a positive equilibrium;
- (b) the first focal value vanishes;
- (c) $P = 0$.

Furthermore, Hofbauer and So [10] conjectured that condition (c) might be replaced by the condition:

- (c') the second focal value vanishes.

In the recent paper [3], we refuted both conjectures by proving the following theorems:

THEOREM 1.1. *In the case of a heteroclinic cycle on the boundary of the carrying simplex of a three-dimensional competitive LV system, the conditions:*

- (a) *there is a pair of purely imaginary eigenvalues at a positive equilibrium;*
- (b) *the first focal value vanishes;*
- (c') *the second focal value vanishes;*

do not imply,

(c) $P = 0$.

In particular, the conditions (a), (b) and (c') do not imply that the interior equilibrium is a center.

THEOREM 1.2. *In the case of a heteroclinic cycle on the boundary of the carrying simplex of a three-dimensional competitive LV system, the conditions:*

- (a) *there is a pair of purely imaginary eigenvalues at a positive equilibrium;*
- (b) *the first focal value vanishes;*
- (c) $P = 0$;

do not imply the condition,

(c') *the second focal value vanishes.*

In particular, the conditions (a), (b) and (c) do not imply that the interior equilibrium is a center.

In [3] we conjectured that in the case of a heteroclinic cycle on the boundary of the carrying simplex of a three-dimensional competitive LV system, the conditions (a), (b), (c), and (c') do *not* imply the condition:

(d) the third focal value vanishes.

In particular, the conditions (a), (b), (c), and (c') do not imply that the interior equilibrium is a center.

In this paper we present an example of a three-dimensional competitive LV system with a heteroclinic cycle for class 27 in Zeeman's classification, which proves this conjecture.

We denote by \mathbb{R}_+^3 and $\text{Int}\mathbb{R}_+^3$ the closed and open positive cone, respectively. The restriction of system (1) to the i th coordinate axis is the logistic equation $\dot{x}_i = x_i(r_i - a_{ii}x_i)$, which has a fixed point R_i at the carrying capacity r_i/a_{ii} . Note that we are abusing notation here, allowing R_i to denote a point in \mathbb{R}_+ or in \mathbb{R}_+^3 as dictated by the context.

It is easy to see that the origin is a repelling fixed point of system (1), and that the basin of repulsion of 0 in \mathbb{R}_+^3 is bounded. The boundary of that basin is called the carrying simplex of system (1), and is denoted by Σ . We refer to Hirsch [6] and Zeeman [16] for more details.

A vector x is called positive if $x \in \mathbb{R}_+^3$, strictly positive if $x \in \text{Int}\mathbb{R}_+^3$. Two points $u, v \in \mathbb{R}^3$ are related if either $u - v$ or $v - u$ is strictly positive. A set S is called balanced if no two distinct points of S are related. The unit simplex, Δ , in \mathbb{R}_+^3 has the standard meaning of $\Pi \cap \mathbb{R}_+^3$, where Π denotes the plane with equation $\sum_{i=1}^3 x_i = 1$.

The following theorem of Hirsch [6] shows that Σ is topologically and geometrically simple and that all the nonzero equilibria and other ω -limit sets of system (1) lie on Σ . In particular, the equilibria R_i and any nontrivial periodic orbit lie on Σ .

THEOREM 1.3. (Hirsch) *Given system (1), every trajectory in $\mathbb{R}_+^3 \setminus \{0\}$ is asymptotic to one in Σ , and Σ is a balanced Lipschitz submanifold, homeomorphic to the unit simplex in \mathbb{R}_+^3 by radial projection.*

By Theorem 1.1 the long term dynamics on \mathbb{R}_+^3 is completely determined by the dynamics on Σ . Moreover, Σ can be viewed (via radial projection) as the unit simplex Δ , which can then be removed from the ambient \mathbb{R}_+^3 and pictured as an equilateral triangle.

If there is no equilibrium in the interior of the carrying simplex Σ , then the dynamics of system (1) is trivial: every orbit converges to the boundary [8]. Therefore we are interested only in the case where system (1) has a positive equilibrium in the interior of Σ . Without loss of generality, we can assume, as indicated by the context, that $E = (1, 1, 1)$ is a positive equilibrium of system (1) and E has no zero eigenvalues.

2. Example for Class 27 with a heteroclinic cycle

In this section, we present an example of a three-dimensional competitive LV system with a heteroclinic cycle for class 27 in Zeeman's classification, which show that: the conditions (a) there is a pair of purely imaginary eigenvalues at an interior equilibrium, (b) the first focal value vanishes, (c') the second focal value vanishes, and (c) the heteroclinic cycle is neutrally stable do *not* imply (d) the third focal value vanishes. In particular, the conditions (a), (b), (c'), and (c) do not imply that the interior equilibrium is a center.

EXAMPLE. Consider the three-dimensional competitive LV system

$$\dot{x}_i = x_i[A(x - E)]_i, \quad i = 1, 2, 3, \quad (2)$$

where

$$A = (a_{ij}) = \begin{pmatrix} -1 & -\frac{3}{2} & \lambda \\ n & -1 & \mu \\ -1 & -3 & -2 \end{pmatrix}$$

with three negative parameters μ , λ and n . By elementary linear algebra, a necessary condition that A has a negative real eigenvalue and a pair of purely imaginary eigenvalues is

$$\det(A) = (M_{23} + M_{13} + M_{12}) \cdot \text{tr}A,$$

where $\text{tr}(A) = \sum_{i=1}^3 a_{ii}$, $M_{23} = a_{22}a_{33} - a_{23}a_{32}$, $M_{13} = a_{11}a_{33} - a_{13}a_{31}$ and $M_{12} = a_{22}a_{11} - a_{12}a_{21}$. A simple calculation yields that

$$\mu = \mu(n, \lambda) := -\frac{12}{7} - \frac{2}{7}n + \frac{2}{7}n\lambda - \frac{2}{7}\lambda. \quad (3)$$

Let $y_i = x_i - 1$, $i = 1, 2, 3$, and set $z = Ty$, where $y = (y_1, y_2, y_3)^T$, $z = (z_1, z_2, z_3)^T$, and

$$T = \begin{pmatrix} n & 3 & -\frac{12}{7} - \frac{2}{7}n + \frac{2}{7}n\lambda - \frac{2}{7}\lambda \\ -1 & -3 & 2 \\ \frac{6}{7} - \frac{6}{7}n + \frac{6}{7}n\lambda - \frac{6}{7}\lambda & 3 - 3\lambda & \frac{18}{7} + \frac{3}{7}n - \frac{3}{7}n\lambda - \frac{18}{7}\lambda \end{pmatrix}.$$

The system (2) is transformed into a new one whose linear part is in the block diagonal form

$$\text{linear part} = \begin{pmatrix} \frac{2+5n}{2(-1+n)} & \frac{-8n\lambda + 4n^2\lambda + 3n^2 + 22n + 4\lambda + 24}{14(-1+n)} & 0 \\ -\frac{1+6n}{2(-1+n)} & -\frac{2+5n}{2(-1+n)} & 0 \\ 0 & 0 & -4 \end{pmatrix} \begin{pmatrix} z_1 \\ z_2 \\ z_3 \end{pmatrix}.$$

This can be reduced to the two-dimensional case by computing the center manifold

$$\begin{aligned} z_3 = F(z_1, z_2) = & f_1(z_1, z_2) + f_2(z_1, z_2) + f_3(z_1, z_2) + f_4(z_1, z_2) \\ & + f_5(z_1, z_2) + f_6(z_1, z_2) + h.o.t., \end{aligned}$$

where $f_i(z_1, z_2) = \sum_{j=0}^i c_{ij} z_1^{i-j} z_2^j$, $i = 1, 2, 3, 4, 5, 6$, and h.o.t. denotes the terms with order greater than or equal to seven. Solving for the c_{ij} 's and substituting by appealing to the method in [11] one obtains the following rather complicated and lengthy expressions for the first focal value $LV_1(n, \lambda)$ and the second focal value $LV_2(n, \lambda)$:

$$LV_1(n, \lambda) = \frac{f_1(n, \lambda)}{f_2(n, \lambda)} \quad \text{and} \quad LV_2(n, \lambda) = \frac{g_1(n, \lambda)}{g_2(n, \lambda)},$$

where

$$\begin{aligned} f_1(n, \lambda) = & 16(-3144 + 12724n + 384n^5\lambda^4 - 1104\lambda \\ & - 1873n^3 - 13095n^4 + 41444n\lambda - 22701n^4\lambda^2 \\ & - 28578n^4\lambda + 14105n^3\lambda^2 - 4843n^3\lambda - 2106n^5 \\ & + 11490n\lambda^3 - 19886n^2\lambda^3 - 2816n^4\lambda^4 + 18654n^3\lambda^3 \\ & - 13072n^4\lambda^3 + 5856n^3\lambda^4 + 7494n^2 - 2248n^2\lambda \\ & - 27153n^2\lambda^2 + 35413n\lambda^2 + 2226\lambda^2 - 4512n^2\lambda^4 \\ & + 800n\lambda^4 - 4671n^5\lambda + 1734\lambda^3 \\ & + 288\lambda^4 - 1890n^5\lambda^2 + 1080n^5\lambda^3), \end{aligned}$$

$$\begin{aligned} f_2(n, \lambda) = & 62208n^5\lambda^3 + 139968n^5\lambda^2 + 104976n^5\lambda \\ & + 26244n^5 + 51840n^4\lambda^3 + 2674944n^4\lambda^2 + 3924936n^4\lambda \\ & + 1460916n^4 + 17280n^3\lambda^3 + 1744416n^3\lambda^2 + 33593292n^3\lambda \\ & + 24221025n^3 + 2880n^2\lambda^3 + 432864n^2\lambda^2 + 16147350n^2\lambda \\ & + 103760514n^2 + 240n\lambda^3 + 47916n\lambda^2 + 2655288n\lambda \\ & + 32595372n + 8\lambda^3 + 146520\lambda + 1992\lambda^2 + 2661336, \end{aligned}$$

$g_1(n, \lambda)$ and $g_2(n, \lambda)$ are given in the Appendix.

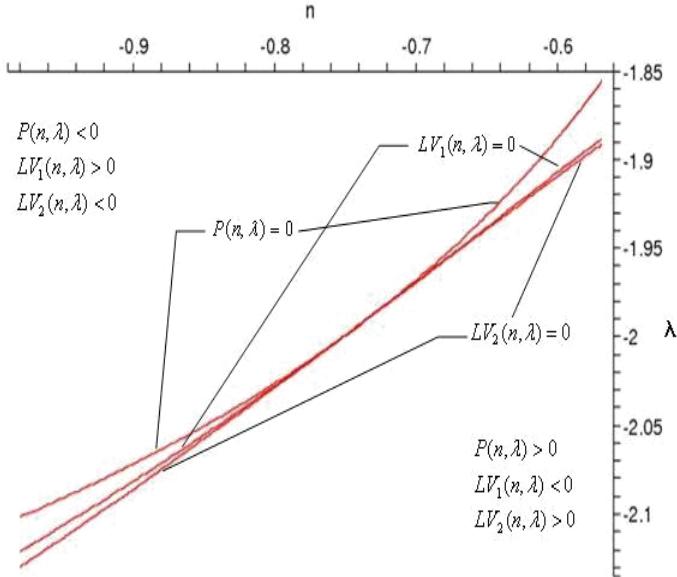

Figure 2: Three curves $P(n, \lambda) = 0$, $LV_1(n, \lambda) = 0$ and $LV_2(n, \lambda) = 0$ intersect at the point $(n_0, \lambda_0) = (-0.75, -2)$.

We computed $LV_1(n, \lambda)$ and $LV_2(n, \lambda)$ as rational functions by using the computer algebraic system Maple. The expression of $P(n, \lambda)$ (i.e., the characteristic number of the heteroclinic cycle) is given as follows:

$$\begin{aligned} P(n, \lambda) = & -(-n(5/2 - \lambda) - 19/7 + 5n/7 + 2n\lambda/7 - 2\lambda/7) \\ & (15/7 - 15n/7 - 6n\lambda/7 + 6\lambda/7)(-2\lambda - 5/2) \\ & -(11/7 - 15n/14 - 3n\lambda/7 + 10\lambda/7) \\ & (-7/2 - \lambda)(17/7 + 11n/7 - 4n\lambda/7 + 4\lambda/7). \end{aligned}$$

A straightforward calculation yields that $LV_1(n, \lambda)$ and $LV_2(n, \lambda)$ have a unique root $(n_0, \lambda_0) = (-0.75, -2) \in U_\varepsilon$, the ε -neighborhood ($\varepsilon = 10^{-5}$) of the point $(-0.75, -2)$ (see Figure 2, above).

Now, we choose $n = n_0$ and $\lambda = \lambda_0$ and adjust $\mu = \mu(n_0, \lambda_0) = -\frac{12}{7} - \frac{2}{7}n_0 + \frac{2}{7}n_0\lambda_0 - \frac{2}{7}\lambda_0$ which keeps the linear part of system (2) in a center-focus form. Noting that $P(n_0, \lambda_0) = 0$, $LV_1(n_0, \lambda_0) = 0$, $LV_2(n_0, \lambda_0) = 0$, and

$$LV_3(n_0, \lambda_0) = \frac{794314633104083832799}{23397286781621005120311720} > 0.$$

Moreover, $\det(A) < 0$ for $(n, \lambda) \in U_\varepsilon$, and $\mu = \mu(n, \lambda) < 0$ for $(n, \lambda) \in U_\varepsilon$. It follows that for $(n, \lambda) \in U_\varepsilon$ and $\mu = \mu(n, \lambda)$ system (2) is a competitive system that satisfies the condition of the eigenvalues; that is, for $(n, \lambda) \in U_\varepsilon$ and $\mu = \mu(n, \lambda)$, the equilibrium E of system (2) has a negative real eigenvalue and a pair of purely imaginary

eigenvalues. Since for $(n, \lambda) \in U_\varepsilon$ and $\mu = \mu(n, \lambda)$, $R_{12} = 1$, $R_{13} = -1$, $R_{21} = -1$, $R_{23} = 1$, $R_{31} = 1$, $R_{32} = -1$ (where $R_{ij} = \text{sgn}(\alpha_{ij})$ with $\alpha_{ij} = r_i a_{ji}/a_{ii} - r_j$), then system (2) with $(n, \lambda) \in U_\varepsilon$ and $\mu = \mu(n, \lambda)$ belongs to class 27 in Zeeman's classification. By the above discussion, we have the following theorem.

THEOREM 2.1. *In the case of a heteroclinic cycle on the boundary of the carrying simplex of three-dimensional competitive Lotka-Volterra systems, the conditions (a), (b), (c), and (c') do not imply (d).*

In particular, the conditions (a), (b), (c), and (c') do not imply that the interior equilibrium is a center.

3. Appendix: The explicit expressions for the polynomials g_1 and g_2

The polynomials g_1 and g_2 are as follows:

$$\begin{aligned}
